

CHAIR ARM WITH AN ADJUSTABLE HEIGHT

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to a chair arm, and more
5 particularly to a chair arm with an adjustable height.

2. Description of Related Art

A conventional chair arm with an adjustable height in
accordance with the prior art shown in Fig. 8 comprises an inner post
(6) adapted to be secured on a chair, an outer post (63) slidably
10 receiving the inner post (6), a securely connected to the outer post (63)
and a clutch (8) pivotally connected to the outer post for selectively
engaging to the inner post (6) to hold the outer post (63) in place.

An adjust seat (61) is securely received in the inner post (6). A
passage (611) is longitudinally defined in the adjust seat (61) and a
15 series of slots (612) is laterally defined in an inner periphery of the
passage (612). A slider (62) is partially slidably received in the passage
(611). The slider (62) has a top end secured on the outer post (63) that
has a top end adapted to be connected to a cushion (not shown) of the
chair. The slider (62) includes a channel (621) defined in one side
20 thereof for receiving the actuator (7). The actuator (7) has a groove (71)
longitudinally defined therein and multiple bolts (72) extending
through the groove (71) and screwed into the slider (62) such that the
actuator (7) can be reciprocally longitudinally moved relative to the

slider (62). The actuator (7) includes a handle (73) secured thereon and extending through the outer post (63) for user to upward driving the actuator (7). A spring (74) is mounted between the slider (62) and the actuator (7) for providing a restitution force to the actuator (7) after
5 being upward moved. A clutch (8) is pivotally mounted between the slider (62) and the actuator (7). The clutch (8) has a stopper (81) extending therefrom. The stopper (81) is selectively engaged to a corresponding one of the series of slots (612) in the adjust seat (61) to hold the outer post (63) in place when being adjusted to a suitable
10 height. The actuator (7) has a raised portion (75) extending therefrom and corresponding to the clutch (8) for driving the clutch (8) and make the stopper (81) detach from the adjust seat (61).

To adjust the height of the conventional chair arm, the actuator (7) is upward moved to make the raised portion (75) press the clutch
15 (8). The outer post (63) can be slidably moved relative to the inner post (6) to adjust the height of the chair arm when the clutch (8) is pressed and the stopper (81) is disengaged relative to the series of slots (612). The handle (73) is released when the outer post (63) extends to a suitable height and the stopper (81) engaged to the slots (612) again.

20 However, the conventional chair arm has a complicated structure for adjusting the height thereof. Consequently, the manufacturing processes are complicated and the manufacturing cost is high.

Furthermore, the actuator (7) is moved to press the clutch (8) to make the stopper (81) detach from the slot (612) in the adjust seat (61). The height of the conventional chair arm may not be adjusted when the raised portion (75) and the clutch are worn and torn.

5 The present invention has arisen to mitigate and/or obviate the disadvantages of the conventional chair arm that has an adjustable height.

SUMMARY OF THE INVENTION

 The main objective of the present invention is to provide an
10 improved chair arm with an adjustable height.

 To achieve the objective, the chair arm in accordance with the present invention comprises an inner post having a first end adapted to be secured on a chair and a second opposite to the first end of the inner post. The inner post includes a first slot longitudinally defined
15 therein near the second end of the inner post and extending through the inner post. The first slot has two opposite sides each having a series of first indentations defined in the inner post. An end piece is attached to the second end of the inner post for closing the inner post and extending into the inner post. The end piece includes a channel defined
20 therein and corresponding to the first slot in the inner post. An outer post is sleeved on the inner post and the inner post partially received in the outer post. The outer post has a through hole defined therein and communicating with the first slot when the outer post partially

receiving the inner post. The outer post has a top end adapted to be securely connected to a cushion of the chair. A locking device is reciprocally slidably mounted in the through hole and extending into the inner post to selectively hold the outer post in place.

5 Further benefits and advantages of the present invention will become apparent after a careful reading of the detailed description with appropriate reference to the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a perspective view of a chair arm with an adjustable
10 height in accordance with the present invention;

Fig. 2 is an exploded perspective view of the chair arm in Fig.
1;

Fig. 3 is a bottom cross-sectional view of the chair arm in Fig. 1;

Fig. 4 is a partially front cross-sectional view of the chair arm
15 in Fig. 1;

Fig. 5 is another bottom cross-sectional view of the chair arm in
Fig. 1;

Fig. 6 is a partially front cross-sectional view of the chair arm
in Fig. 1 when the button is pressed;

20 Fig. 7 is an operational side plan view of the chair arm of the present invention; and

Fig. 8 is a front cross-sectional view of a conventional chair arm in accordance with the prior art.

DETAILED DESCRIPTION OF THE INVENTION

Referring to the drawings and initially to Figs. 1-4, a chair arm with an adjustable height in accordance with the present invention comprises inner post (1), an outer post (2) partially receiving the inner post (1), a locking device (3) extending through the inner post (1) and the outer post (2) for selectively positioning the outer post (2) relative to the inner post (1).

The inner post (1) includes a first end adapted to be secured on a chair and a second end opposite to the first end of the inner post (1).

10 The inner post (1) has a first slot (11) longitudinally defined in the inner post (1) near the second end of the inner post (1) and extending through the inner post (1). The first slot (11) has two opposite longitudinal sides each having a series of first indentations (111). The inner post (1) has a second slot (12) longitudinally defined therein near the second end of the inner post (1) and corresponding to the first slot (11) in the inner post (1). The second slot (12) extends through the inner post (1) and has two opposite longitudinal sides each having a series of second indentations (121) defined in the inner post (1). The series of second indentations (121) interactively correspond to the series of first indentations (111).

20 An end piece (13) inserted into the inner post (1) from the second end of the inner post (1) and secured on the second end of the inner post (1). The end piece (13) includes a cover (131) attached to the

second end of the inner post (1) for closing the inner post (1) and two rails (132) downward extending from the cover (131) into the inner post (1) such that a channel (133) is defined between the two rails (132). The channel (133) corresponds to the first slot (11) and the
5 second slot (12) in the inner post (1).

The outer post (2) is telescopically sleeved on the inner post (1). The outer post (2) includes a through hole (21) laterally defined therein and communicating with the first slot (11) when the outer post (2) is sleeved on the inner post (1). The outer post (2) has an enlarged portion
10 (22) formed on a top end of the outer post (2) and adapted to be securely connected to a cushion (4) of the chair.

The locking device (3) includes a button (31) reciprocally movably received in the through hole (21) in the outer post (2) and partially extending out of the outer post (2). A protrusion (35) laterally
15 extends from the button (31) and has a width slightly smaller than that of the first slot (11) in the inner post (1). The protrusion (35) is slidably received in the first slot (11) in the inner post (1). The protrusion (35) includes two opposite sides each having at least one buckle (34) laterally extending therefrom. The buckle (34) is selectively engaged to
20 a corresponding one of the series of first indentations (111) to hold the outer post (2) in place. In the preferred embodiment of the present invention, each opposite sides of the protrusion (34) has two buckles (34) extending therefrom. A shank (32) longitudinally extends from the

protrusion (35) through the channel (133) and the second slot (12) in the inner post (1). The shank (32) has a width slightly smaller than that of the second slot (12) such that the shank (32) is partially slidably received in the second slot (12) when adjusting the height of the chair arm of the present invention. The shank (32) has two opposite sides each has a stopper (33) laterally extending therefrom near a free end of the shank (32) and abutting the rails (132) of the end piece (13) to prevent the locking device (3) from detaching from the chair arm. Each stopper (33) is selectively received in a corresponding one of the series of second indentations (121) to guide the each buckle (34) aligning with a corresponding one of the first indentations (111) and enhance the position purpose of the locking device (3). A resilient member (37) is compressively sleeve on the shank (32) between the protrusion (35) and the rails (132) to provide a restitution force to the locking device (3) after being pressed. The resilient member (37) has a first end abutting the protrusion (35) and a second end abutting the rails (132) of the end piece (13). In the preferred embodiment of the present invention, the resilient member (37) is a spring.

With reference to Fig. 2 and 5, the chair arm in accordance with the present invention further comprises two pushers (5) each mounted in two opposite sides of the inner post (1) and abutting against the inner periphery of the outer post (2) to prevent the outer post (2) from shaking due to a gap between the inner post (1) and the outer post (2).

The pusher (5) includes a seat (51) secured in the inner post (1), a spring (52) compressively received in the seat (51) and a steel ball (53) partially received in the seat (51). The steel ball (53) extends to abut the inner periphery of the outer post (2).

5 To operate the chair arm of the present invention, with reference to Figs. 5 and 6, the button (31) is inwardly pressed relative to the chair arm, thereby the buckles (34) and the stoppers (33) are respectively detached from the first indentations (111) and the second indentations (121). Consequently, the protrusion (35) and the shank (32)
10 are respectively freely received in the first slot (11) and the second slot (12), and the outer post (2) can be moved relative to the inner post (1) to adjust the height of the chair arm of the present invention.

 As described above, the structure of the chair arm has been advantageously altered, thereby the costs of manufacturing and
15 assembling are reduced and the user only needs to press the button (31) when adjusting the height of the chair arm. The bolts of the conventional adjustable chair arm are unnecessary to the present invention, thereby the manufacturing processes are simplified to save the time of manufacture the chair arm in accordance with the present
20 invention.

 Although the invention has been explained in relation to its preferred embodiment, it is to be understood that many other possible modifications and variations can be made without departing from the

spirit and scope of the invention as hereinafter claimed.
